17 PATIENT COUNSELING INFORMATION

* Sections or subsections omitted from the full prescribing information are not listed

Xermelo was studied in a double-blind, placebo-controlled clinical trial of 90 patients with metastatic neuroendocrine tumors and carcinoid syndrome diarrhea. Patients reported constipation and/or severe, persistent or worsening abdominal pain. Discontinue Xermelo if severe constipation or abdominal pain develops. (5.1)

5.1 Constipation

Most common adverse reactions (≥5%) are nausea, headache, increased GGT, depression, flatulence, decreased appetite, peripheral edema, and pyrexia. (6.1)

To report SUSPECTED ADVERSE REACTIONS, contact TerSera Therapeutics LLC at 1-844-334-4035 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch

Drug Interactions

CYP3A4 Substrates (e.g., midazolam) and CYP2B6 Substrates (e.g., bupropion, efavirenz); Efficacy of concomitant drugs may be decreased; monitor patients’ response and consider increasing the dosage of the concomitant drug, if necessary. (7.1)

See 17 for PATIENT COUNSELING INFORMATION.

Revised: 10/2020

---

### Xermelo (telotristat ethyl) Tablets, for oral use.

**INDICATIONS AND USAGE**

Xermelo is indicated for the treatment of carcinoid syndrome diarrhea in combination with somatostatin analog (SSA) therapy in adults inadequately controlled by SSA therapy.

**Dosage and Administration**

The recommended dosage of Xermelo in adult patients is 250 mg three times daily for patients whose diarrhea is inadequately controlled by SSA therapy. (2)

- Take Xermelo with food. (2)
- Short-acting octreotide at least 30 minutes after administering Xermelo. (2, 7.3)
- Discontinue Xermelo if severe constipation develops. (2, 5.1)

**Contraindications**

None. (4)

**Warnings and Precautions**

Constipation: Xermelo reduces bowel movement frequency; monitor patients for constipation and/or severe persistent or worsening abdominal pain. Discontinue Xermelo if severe constipation or abdominal pain develops. (5.1)

**Adverse Reactions**

Most common adverse reactions (≥5%) are nausea, headache, increased GGT, depression, flatulence, decreased appetite, peripheral edema, and pyrexia. (6.1)

*Incidence of at least 5% in the Xermelo group and at an incidence greater than placebo

Performance of the above clinical trials was conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

Xermelo was studied in a double-blind, placebo-controlled clinical trial of 90 patients with metastatic neuroendocrine tumors and carcinoid syndrome diarrhea. Patients reported between 4 to 12 bowel movements daily despite the use of SSA therapy at a stable dose for at least 3 months [see Clinical Studies (14)]. Placebo or Xermelo 250 mg was administered three times daily for 12 weeks. Concomitant anti-diarrheal medications (e.g., loperamide) were used by 43% (36% and 51% in the placebo and Xermelo group, respectively), pancreatic enzyme replacement medications by 39% (36% and 42% in the placebo and Xermelo group, respectively), and opioid analgesics by 29% (24% and 33% in the placebo and Xermelo group, respectively) of patients during the 12-week double-blind period of the trial.

Table 1 below lists adverse reactions occurring at an incidence of at least 5% in the Xermelo group (N=45) and at an incidence greater than placebo (N=45) during the 12-week placebo-controlled period of the trial.

---

In another placebo-controlled clinical trial of patients with carcinoid syndrome diarrhea and less than 4 bowel movements per day, the following additional adverse reactions, not listed in Table 1, of abdominal pain (including upper and lower abdominal pain, abdominal distention and gastrointestinal pain) and constipation were reported in at least 5% of patients in the Xermelo treated group and at an incidence greater than placebo [see Warnings and Precautions (5.1)].
Less Common Adverse Reactions: The following is a list of adverse reactions occurring in less than 5% of patients receiving Xermelo during the 12-week placebo-controlled period of the clinical trial: Investigations: increased alkaline phosphatase, increased alanine aminotransferase, and increased aspartate aminotransferase.

Feculaoma was reported in one patient treated with Xermelo during the 36-week open-label extension period following the 12-week double-blind period of the trial.

DRUG INTERACTIONS
7.1 CYP3A4 Substrates Concomitant use of Xermelo may decrease the efficacy of drugs that are CYP3A4 substrates (e.g., midazolam) by decreasing their systemic exposure. Monitor patients’ response to CYP3A4 substrates when co-administered with Xermelo and consider increasing the dosing of the interacting drug, if necessary [see Clinical Pharmacology (12.3)].

7.2 CYP2B6 Substrates Concomitant use of Xermelo may decrease the efficacy of drugs that are CYP2B6 substrates (e.g., bupropion, efavirenz) by decreasing their systemic exposure. Monitor patients’ response to CYP2B6 substrates when co-administered with Xermelo and consider increasing the dosing of the interacting drug, if necessary [see Clinical Pharmacology (12.3)].

7.3 Short-Aging Ooctreotide Concurrent administration of short-acting octreotide with Xermelo significantly decreased the systemic exposure of telotristat ethyl and telotristat, the active metabolite. If treatment with short-acting octreotide is needed in combination with Xermelo, administer short-acting octreotide at least 30 minutes after administration of Xermelo [see Clinical Pharmacology (12.3)].

8 USE IN SPECIFIC POPULATIONS
8.1 Pregnancy Risk Summary There are no human data with Xermelo use in pregnant women to inform a drug-associated risk. In animal reproduction studies, no effects on embryo-fetal development were observed with the administration of oral telotristat ethyl to rats during organogenesis at doses up to 750 mg/kg/day (approximately 9 times the exposure at the RHD [recommended human dose]). Treatment of pregnant rabbits with oral telotristat ethyl during organogenesis produced maternal toxicity and post-implantation loss at doses of 250 mg/kg/day or higher (approximately 15 times the exposure at the RHD), and reduced fetal weight at 500 mg/kg/ day (approximately 33 times the exposure at the RHD). In a pre- and postnatal development study, an increased incidence of mortality in rat offspring was observed during postnatal days 0 to 4 at the maternal oral dose of 500 mg/kg/day (approximately 5 times the exposure at the RHD), given during organogenesis through lactation (see Data).

The estimated background risk of major birth defects and miscarriage for the indicated population is unknown. All pregnancies have a background risk of birth defect, loss or other adverse outcomes. In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2% to 4% and 15% to 20%, respectively.

Data Animal data
An embryo-fetal development study performed in rats with oral telotristat ethyl at doses up to 750 mg/kg/day (approximately 9 times the AUC [area under the plasma concentration-time curve] for the active metabolite at the RHD) during organogenesis produced no harm to embryo-fetal development. In pregnant rabbits treated orally with telotristat ethyl during organogenesis, an increased incidence of post-implantation loss at doses of 250 and 500 mg/kg/day (approximately 15 times the AUC for the active metabolite at the RHD) and a decrease in fetal weight at 500 mg/kg/day (approximately 33 times the AUC for the active metabolite at the RHD) was observed. The adverse effects on embryo-fetal development were associated with maternal toxicity (impaired weight gain and/or mortality) at 250 and 500 mg/kg/ day. No adverse effects on embryo-fetal development were observed at 125 mg/kg/day (approximately 5 times the AUC for the active metabolite at the RHD).

A pre- and postnatal development study was conducted in rats using oral administration of 100, 200, and 500 mg/kg/day telotristat ethyl during organogenesis through lactation. An increased incidence of pup mortality was observed during postnatal days 0 to 4 at the maternal dose of 500 mg/kg/day (approximately 5 times the AUC for the active metabolite at the RHD). No developmental abnormalities or effects on growth, learning and memory, or reproductive performance were observed through maturation of offspring at maternal doses of up to 500 mg/kg/day in surviving offspring.

8.2 Lactation Risk Summary There are no data on the presence of telotristat ethyl in human or animal milk, the effects on the breastfed infant, or the effects on milk production. The effects of local gastrointestinal and systemic exposure to telotristat ethyl on breastfed infants are unknown. The developmental and health benefits of breastfeeding should be considered along with the mother’s clinical need for Xermelo and any potential adverse effects on the breastfed infant from Xermelo or from the underlying maternal condition.

Clinical Considerations
Monitor the breastfed infant for symptoms of constipation.

8.3 Pediatric Use The safety and effectiveness of Xermelo in pediatric patients have not been established.

8.5 Geriatric Use Of 45 patients in a clinical trial of Xermelo, 19 (42%) patients were 65 years of age and over. No overall differences in safety or effectiveness were observed between these patients and younger patients, and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

8.6 Renal Impairment No dosage adjustment of Xermelo is necessary in patients with mild, moderate or severe renal impairment who are not requiring dialysis. There is no information on Xermelo in patients with end-stage renal disease who require dialysis (eGFR <15 mL/min/1.73 m²).

8.7 Hepatic Impairment Systemic exposure of telotristat ethyl and its active metabolite, telotristat, were substantially increased in patients with moderate hepatic impairment (Child-Pugh Class B) and severe hepatic impairment (Child-Pugh C) (3.2- and 5.0-fold, respectively) compared to patients with normal hepatic function [see Clinical Pharmacology (12.3)]. Xermelo is not recommended in patients with moderate and severe hepatic impairment.

No dosage adjustment of Xermelo is necessary in patients with mild hepatic impairment (Child-Pugh A); however, additional monitoring of Xermelo–associated adverse reactions (e.g., constipation) is recommended in these patients [see Warnings and Precautions (5.1)].

11 DESCRIPTION Xermelo (telotristat ethyl) tablets contain telotristat ethyl as telotristat etiprate, a tryptophan hydroxylase inhibitor. Telotristat ethyl is the hkipurate salt of telotristat ethyl [(S)-ethyl-2-amino-3-(4-(2-amino-6-((R)-1-(4-chloro-2-(3-methyl-1H-pyrazol-1-yl)phenyl)-2,2,2-trifluoroethoxy)pyrimidin-4-yl)phenoxy)propanoate], which undergoes hydrolysis to the active metabolite, (S)-2-amino-3-(4-(2-amino-6-(R)-1-(4-chloro-2-(3-methyl-1H-pyrazol-1-yl)phenyl)-2,2,2-trifluoroethoxy)pyrimidin-4-yl)phenoxy)propanoic acid. The molecular formula of telotristat etiprate is C₂₇H₂₆ClF₃N₆O₃ • C₉H₉NO₃, and its molecular weight is 754.2. The molecular weight of the free base (telotristat ethyl) is 575.0.

Chemical Structure:

Telotristat etiprate is a white to off-white solid. The solubility is a function of pH at 25°C, at pH 1 (0.1N HCl), the solubility is greater than 71 mg/mL, at pH 3 phosphate buffer, the solubility is 0.30 mg/mL, at a pH of 5 to 9, the solubility is negligible. In organic solvents, telotristat etiprate is freely soluble in melanol, soluble in acetone, and sparingly soluble in ethanol. Each Xermelo tablet contains 250 mg of telotristat ethyl (free base) which is equivalent to 328 mg telotristat etiprate. The inactive ingredients of Xermelo tablets include: colloidal silicon dioxide, croscarmellose sodium, hydroxypropyl cellulose, lactose anhydrous, macrogol/PEG, magnesium stearate, polyvinyl alcohol [part hydrolyzed], talc and titanium dioxide.

12 CLINICAL PHARMACOLOGY
12.1 Mechanism of Action Telotristat, the active metabolite of telotristat ethyl, is an inhibitor of tryptophan hydroxylase, which mediates the rate limiting step in serotonin biosynthesis. The intrinsically inhibitory potency of telotristat towards tryptophan hydroxylase is 29 times higher than that of telotristat ethyl. Serotonin plays a role in mediating secretion, motility, inflammation, and sensation of the gastrointestinal tract, and is over-produced in patients with carcinoid syndrome. Through inhibition of tryptophan hydroxylase, telotristat and telotristat ethyl reduce the production of peripheral serotonin, and the frequency of carcinoid syndrome diarrhea.

12.2 Pharmacodynamics In healthy subjects, telotristat ethyl 500 mg three times daily (twice the recommended dosage) for 14 days decreased whole blood serotonin and 24-hour urinary 5-hydroxyindolacetic acid (u5-HIAA) from baseline. A decrease in 24-hour u5-HIAA was observed as early as after 5 days of treatment. In patients with metastatic neuroendocrine tumors and carcinoid syndrome diarrhea, 24-hour u5-HIAA decreased from baseline following 6 and 12 weeks of treatment with Xermelo 250 mg three times a day, whereas placebo did not decrease u5-HIAA.

Cardiac Electrophysiology At a dose 6 times the recommended dose of 250 mg, Xermelo does not prolong the QT interval to any clinically relevant extent.

12.3 Pharmacokinetics Absorption
After a single oral dose of telotristat ethyl to healthy subjects, telotristat ethyl was absorbed and metabolized to its active metabolite, telotristat. Peak plasma concentrations of telotristat ethyl were achieved within 0.5 to 2 hours, and those of telotristat within 1 to 3 hours. Plasma concentrations thereafter declined in a biphasic manner. Following administration of a single 500 mg dose of telotristat ethyl (twice the recommended dosage) under fasted conditions in healthy subjects, the mean Cₘₚ max and AUCₘₚ max were 4.4 ng/mL and 2320 ng•hr/mL, respectively for telotristat. Peak plasma concentrations and AUC of telotristat etiprate and telotristat appeared to be dose proportional following administration of a single dose of telotristat ethyl in the range of 100 mg (0.4 times the lowest recommended dose to 1000 mg [4 times the highest recommended dose]) under fasted conditions.
Following multiple-dose administration of telotristat ethyl 500 mg three times daily, there was negligible accumulation at steady state for both telotristat ethyl and telotristat.

In patients with metastatic neuroendocrine tumors and carcinoid syndrome diarrhea treated with SSA therapy, the median T1/2 for telotristat ethyl and telotristat was approximately 1 and 2 hours, respectively. Following administration of 500 mg telotristat ethyl three times daily, with meals in patients, the mean Cmax and AUC0-inf were approximately 7 ng/mL and 22 ng•hr/mL, respectively, for telotristat ethyl. The mean Cmax and AUC0-inf were approximately 900 ng/mL and 3000 ng•hr/mL, respectively for telotristat.

The pharmacokinetic parameters for both telotristat ethyl and telotristat were highly variable with about 55% coefficient of variation.

Food Effect
Administration of a single 500 mg dose of Xermelo (twice the recommended dose) with food resulted in higher exposure to both telotristat ethyl and telotristat. The systemic exposure to telotristat ethyl, was significantly increased following administration with a high-fat meal, with Cmax and AUC0-inf being 112% and 264% higher, respectively compared to the fasted state.

Following administration of a single 500 mg dose of telotristat ethyl under fed conditions in healthy subjects, the mean Cmax and AUC0-inf were 10.5 ng/mL and 2980 ng•hr/mL, respectively, for telotristat. The mean Cmax and AUC0-inf were 908 ng/mL and 2980 ng•hr/mL, respectively for telotristat under fed conditions [see Dosage and Administration (2)].

Distribution
Both telotristat ethyl and telotristat are greater than 99% bound to human plasma proteins. In vitro data suggests that telotristat is a substrate of P-glycoprotein.

Elimination
Following a single 500 mg oral dose of telotristat ethyl in healthy subjects, the apparent half-life was approximately 0.6 hours for telotristat ethyl and 5 hours for telotristat. The apparent total clearance at steady state (CL/F) following oral dosing with telotristat ethyl 500 mg three times daily for 14 days (twice the recommended dosage) in healthy subjects was 2.7 and 152 L/hr for telotristat ethyl and telotristat, respectively.

Metabolism
After oral administration, telotristat ethyl undergoes hydrolysis via carboxylesterases to telotristat, its active metabolite. Telotristat is further metabolized. Among the metabolites of telotristat, the systemic exposure to an acid metabolite of oxidative deaminated decarboxylated telotristat was about 35% of that of telotristat. In vitro data suggest that telotristat ethyl and telotristat are not substrates for CYP enzymes.

Excretion
Following a single 500 mg oral dose of 14C-telotristat ethyl, 93.2% of the dose was recovered over 240 hours. 92.8% was recovered in the feces, with less than 0.4% being recovered in the urine.

Specific Populations

Age and Sex
Population pharmacokinetic analysis indicated that age (18 to 83 years) and sex do not affect the pharmacokinetics of telotristat.

Renal Impairment
Exposure to telotristat ethyl and its active metabolite, telotristat, was similar in patients with severe renal impairment or end-stage renal disease without dialysis (eGFR < 30 mL/min/1.73 m²) compared with subjects with normal renal function following a single oral dose of Xermelo [see Use in Specific Populations (8.6)]. Xermelo was not studied in patients with end-stage renal disease who require dialysis (eGFR < 15 mL/min/1.73 m²).

Hepatic Impairment
Following a single dose of Xermelo 500 mg, systemic exposure (AUC(0-6hr)) to telotristat ethyl was 2.3- and 3.2-fold higher in subjects with mild (Child-Pugh A) and moderate (Child-Pugh B) hepatic impairment, respectively, than in subjects with normal hepatic function. In subjects with severe (Child-Pugh C) hepatic impairment, following a single Xermelo 250 mg dose, systemic exposure (AUC(0-6hr)) was 4-fold higher than in subjects with normal hepatic function. In these same studies, AUC(0-6hr) to telotristat (active metabolite) was 2.4-, 3.5-, and 5-fold higher in subjects with mild, moderate, and severe hepatic impairment, respectively [see Use in Specific Populations (8.7)].

In patients with metastatic neuroendocrine tumors and carcinoid syndrome diarrhea, population pharmacokinetic analysis indicated that mild hepatic impairment (defined as total bilirubin greater than 1 to 1.5 times the upper limit of normal [ULN]) or AST greater than the ULN did not affect the pharmacokinetics of telotristat.

Drug Interaction Studies

Effect of Telotristat Ethyl on Other Drugs
In vitro studies
Based on in vitro studies, the potential interaction of telotristat ethyl, telotristat, and the acid metabolite of telotristat to inhibit major CYP enzymes (1A2, 2B6, 2C8, 2C9, 2C19, 2D6, 2E1, and 3A4/5) and to induce CYP1A2 is low at the recommended dosage of Xermelo.

Based on in vitro studies, potential induction of CYP2B6 in vivo by Xermelo cannot be ruled out [see Drug Interactions (7.2)].

In vitro telotristat ethyl, but not telotristat, inhibited breast cancer resistance protein (BCRP) at the clinically relevant concentrations. However, in vivo drug interaction potential via inhibition of BCRP is low based on in vitro studies and in vivo findings.

Based on in vitro studies, in vivo drug interaction potential via inhibition of organic cation transporter 1 (OCT1), OCT2, organic anion transporter 1 (OAT1), OAT3, organic anion transporting polypeptide b1b1 (OATP1b1), OATP1b3, or bile salt export pump (BSEP) transporters by telotristat ethyl and telotristat is low at the recommended dosage. Based on in vitro study results, the potential for the acid metabolite of telotristat to inhibit P-gp, BCRP, OCT1, OCT2, OAT1, OAT3, OATP1b1, OATP1b3, BSEP, and MRP2 transporters is low at the recommended dosage.

Midazolam (sensitive CYP3A4 substrate)
Following administration of multiple doses of telotristat ethyl, the systemic exposure to concomitant midazolam was significantly decreased. When 3 mg midazolam was co-administered orally after 5 day treatment with telotristat ethyl 500 mg three times daily (twice the recommended dosage), the mean Cmax and AUC0-inf for midazolam were decreased by 25%, and 48%, respectively, compared to administration of midazolam alone. The mean Cmax and AUC0-inf for the active metabolite, 1'-hydroxymidazolam, were also decreased by 34%, and 48%, respectively. The reduction in the systemic exposure to both midazolam and its active metabolite suggests that the glucuronidation of 1'-hydroxymidazolam may have been increased by telotristat ethyl [see Drug Interactions (7.1)].

Fexofenadine (sensitive P-gp substrate)
In vitro telotristat ethyl, but not telotristat, inhibited P-glycoprotein (P-gp). In healthy volunteers, the Cmax and AUC of fexofenadine increased by 16% when a single 180 mg dose of fexofenadine was co-administered orally with the final dose of telotristat ethyl 500 mg administered three times daily (twice the recommended dosage) for 5 days. Clinically meaningful interactions with P-gp substrates are unlikely.

Effect of Other Drugs on Telotristat Ethyl

Short-Acting Octreotide
The mean Cmax and AUC0-inf of telotristat ethyl were decreased by 86% and 81%, respectively, following administration of a single 500 mg dose of Xermelo (twice the recommended dose), co-administered with short-acting octreotide 200 mcg injected subcutaneously in healthy subjects. 

Omeprazole
The Cmax and AUC0-inf of telotristat ethyl were increased by 68% and 185%, respectively, when a single 250 mg dose of Xermelo was coadministered with a 40 mg dose of omeprazole once a day compared to administration of Xermelo alone. No significant change (<9%) in AUC and Cmax of the active metabolite, telotristat, was observed following coadministration of Xermelo with omeprazole compared to administration of Xermelo alone. These changes in exposure of telotristat ethyl and telotristat are not considered to be clinically meaningful.

Famotidine
The Cmax and AUC0-inf of telotristat ethyl were increased by 22% and 111%, respectively, when a single 250 mg dose of Xermelo was coadministered with a 40 mg dose of famotidine twice daily. No significant change (<5%) in AUC and Cmax to the active metabolite, telotristat, was observed following coadministration of Xermelo with famotidine compared to administration of Xermelo alone. These changes in exposure are not considered to be clinically meaningful.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility
In a 26-week study in transgenic (Tg.rasH2) mice, telotristat ethyl was not tumorigenic at oral doses up to 300 mg/kg/day (approximately 12 to 19 times the AUC for the active metabolite at the RHD).

In a 2-year carcinogenicity study in Sprague-Dawley rats, telotristat ethyl was not tumorigenic at oral doses up to 170 mg/kg/day (approximately 2 to 5 times the AUC for the active metabolite at the RHD).

Telotristat ethyl was negative in the in vitro Ames test, the in vitro chromosomal aberration test using Chinese hamster ovary cells, and the in vivo micronucleus test.

Telotristat ethyl at oral doses up to 500 mg/kg/day (approximately 5 times the AUC for the active metabolite at the RHD) was found to have no effect on fertility and reproductive performance of male or female rats.

14 CLINICAL STUDIES

A 12-week double-blind, placebo-controlled, randomized, multicenter trial of Xermelo was conducted in adult patients with a well-differentiated metastatic neuroendocrine tumor and carcinoid syndrome diarrhea who were having between 4 to 12 daily bowel movements despite the use of SSA therapy at a stable dose for at least 3 months. Patients were randomized to placebo or treatment with Xermelo 250 mg three times daily.

Study medication was administered within 15 minutes before or within 1 hour after a meal or snack [see Dosage and Administration (2)]. All patients were required to stay on their baseline SSA regimen and were allowed to use rescue medication (short-acting octreotide) and antidiarrheals (e.g., loperamide) for symptomatic relief. All patients were randomized to placebo or treatment with Xermelo 250 mg three times daily.

The primary efficacy endpoint was the change from baseline in the number of daily bowel movements averaged over the 12-week treatment period. The analysis results can be found in Table 2 below. The average was based on the number of days with valid, non-missing data. When a patient had more than 6 weeks of missing data, the change from baseline was considered equal to zero. A week of missing data was defined as a patient missing at least 4 days of diary data in that week.
In the 12-week study, a difference in average weekly reductions in bowel movement frequency between Xermelo and placebo was observed as early as 1 to 3 weeks, and persisted for the remaining 9 weeks of the study.

To aid in the interpretation of the bowel movement reduction results, the proportion of patients reporting any particular level of reduction in overall average bowel movement frequency is depicted in Figure 1 below. For example, 33% of patients randomized to Xermelo and 4% of patients randomized to placebo experienced a reduction in overall average bowel movements from baseline of at least 2 bowel movements per day.

**Figure 1: Cumulative Proportion of Patients with Carcinoid Syndrome Diarrhea Reporting Change in Overall Average Bowel Movement Frequency**

</table>

CL=confidence limit; SD=standard deviation.

*Baseline Bowel Movements/Day was assessed over the 3-4 week screening/run-in period.

* Statistical tests used a blocked 2-sample Wilcoxon Rank Sum statistic (van Elteren test) stratified by the u5-HIAA stratification at randomization. CLs were based on the Hodges-Lehmann estimator of the median paired difference.

In the 12-week study, a difference in average weekly reductions in bowel movement frequency between Xermelo and placebo was observed as early as 1 to 3 weeks, and persisted for the remaining 9 weeks of the study.

To aid in the interpretation of the bowel movement reduction results, the proportion of patients reporting any particular level of reduction in overall average bowel movement frequency is depicted in Figure 1 below. For example, 33% of patients randomized to Xermelo and 4% of patients randomized to placebo experienced a reduction in overall average bowel movements from baseline of at least 2 bowel movements per day.

**Figure 1: Cumulative Proportion of Patients with Carcinoid Syndrome Diarrhea Reporting Change in Overall Average Bowel Movement Frequency**

Other symptoms of carcinoid syndrome (abdominal pain or flushing) did not show improvement in the comparison of Xermelo to placebo.

The average number of daily short-acting octreotide injections used for rescue therapy over the 12-week double-blind treatment period was 0.3 and 0.7 in the Xermelo and placebo groups, respectively. In the subgroup of patients who received short-acting octreotide injections, observed reductions in the number of bowel movements per day and treatment differences were generally consistent with the reductions and differences observed in patients who did not receive rescue therapy, and were similar to the overall data presented in Table 2 above [see Dosage and Administration (2), Drug Interactions (7.2)].

A third randomized treatment arm of Xermelo 500 mg three times daily did not demonstrate additional treatment benefit on the primary endpoint and had a greater incidence of adverse reactions than Xermelo 250 mg three times daily. Therefore, Xermelo 500 mg three times daily is not recommended [see Dosage and Administration (2)].

### 16 HOW SUPPLIED/STORAGE AND HANDLING

**How Supplied**

- 250 mg tablet: white to off-white coated oval tablet with “T-E” debossed on one side and “250” debossed on the other side.

Xermelo is dispensed in a monthly case for a total of 28 days of therapy. Each monthly case contains four weekly packs. Each weekly pack contains 21 tablets.

**Storage**

Store at 25°C (77°F); excursions permitted to 15°C to 30°C (59°F to 86°F) [see USP Controlled Room Temperature].

### 17 PATIENT COUNSELING INFORMATION

**Advising patients:**

- If they experience severe constipation or severe persistent or worsening abdominal pain, to discontinue Xermelo and contact their healthcare provider [see Warnings and Precautions (5.1)].
- To take Xermelo with food [see Clinical Pharmacology (12.3), Clinical Studies (14)].
- When short-acting octreotide is used in combination with Xermelo, administer short-acting octreotide at least 30 minutes after administering Xermelo [see Drug Interactions (7.3)].
- If a dose is missed, take the next dose at the regular time. Do not take 2 doses at the same time to make up for a missed dose.
